

Handling User Authentication

Write-up

1. I set up a standalone project to do unit testing of the user authentication class which is used in the main web application.
2. The objective is to create a JUnit class that will test all aspects of the authentication class.
3. As a part of developing an ecommerce web application, a test-suite is being created to do unit testing of all backend components in the web application.
4. This project will test the user authentication class (via user name and password).
5. This project will be a standalone Java application, since Junit does not directly test servlets or web pages. We are only testing the classes that have the business logic.
